Bongora, Guwahati-781015**

The Concept of Stability

(a) Stable

(b) Neutral

(c) Unstable

The concept of stability can be illustrated by a cone placed on a plane horizontal surface.

A necessary and sufficient condition for a feedback system to be stable is that all the poles of the system transfer function have negative real parts.

A system is considered marginally stable if only certain bounded inputs will result in a bounded output.

The Concept of Stability

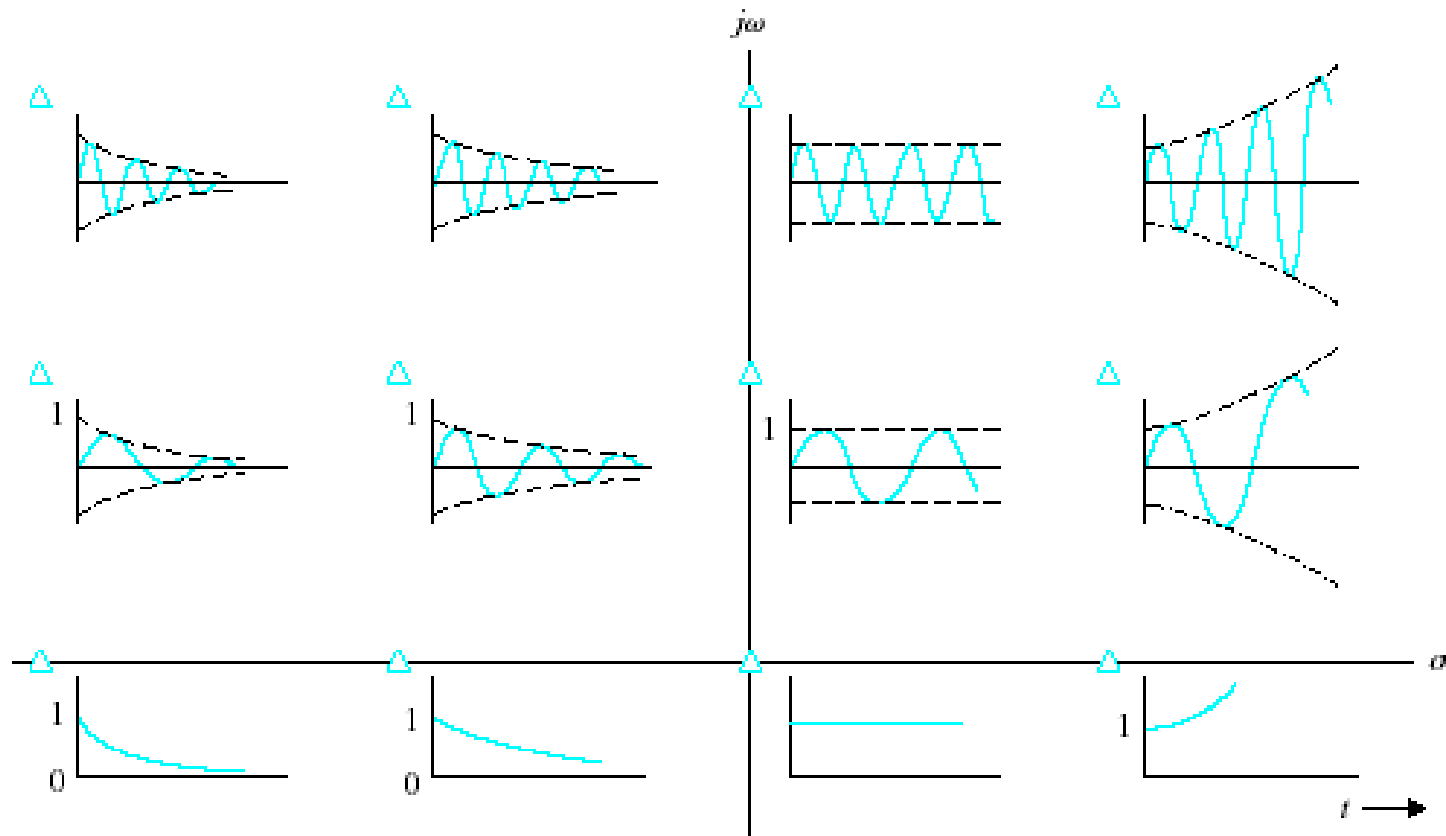

BIBO Stability: If response is bounded for all bounded input

System is BIBO stable if impulse response is bounded

Absolute stability: Response reach to zero for zero inputs and any initial conditions

An LTI system is a absolute stable if it is a BIBO stable

The s-Plane Pole Location and The Transient Response

Impulse response for various root locations in the s-plane
(The conjugate root is not shown.)

Response is unbounded when $Re(pole) > 0$.

Stability of a Closed-loop Systems

- Stability depends on location of the poles of the system
- Poles of closed-loop system are the roots of the characteristic equation, $1 + G(s)H(s) = 0$

Classical Techniques for Stability Analysis

Following techniques are used for stability analysis for closed-loop systems using loop transfer function, $G(s)H(s)$

1. Time domain techniques:

- i) Routh-Hurwitz criterion
- ii) Root locus Technique

2. Frequency domain techniques:

- i) Bode Plots
- ii) Nyquist Stability Criterion

The Routh-Hurwitz Stability Criterion

It was discovered that all coefficients of the characteristic polynomial must have the same sign and non-zero if all the roots are in the left-hand plane.

These requirements are necessary but not sufficient. If the above requirements are not met, it is known that the system is unstable. But, if the requirements are met, we still must investigate the system further to determine the stability of the system.

The Routh-Hurwitz criterion is a necessary and sufficient criterion for the stability of linear systems.

The Routh-Hurwitz Stability Criterion

Characteristic equation,
 $q(s) = 1 + G(s)H(s) = 0$

Routh array

$$a_n s^n + a_{n-1} s^{n-1} + a_{n-2} s^{n-2} + \cdots + a_1 s + a_0 = 0$$

s^n	a_n	a_{n-2}	a_{n-4}
s^{n-1}	a_{n-1}	a_{n-3}	a_{n-5}
s^{n-2}	b_{n-1}	b_{n-3}	b_{n-5}
s^{n-3}	c_{n-1}	c_{n-3}	c_{n-5}
•	•	•	•
•	•	•	•
•	•	•	•
s^0	h_{n-1}		

The Routh-Hurwitz criterion states that the number of roots of $q(s)$ with positive real parts is equal to the number of changes in sign of the first column of the Routh array.

$$b_{n-1} = \frac{(a_{n-1})(a_{n-2}) - a_n(a_{n-3})}{a_{n-1}} = \frac{-1}{a_{n-1}} \left| \begin{array}{cc} a_n & a_{n-2} \\ a_{n-1} & a_{n-3} \end{array} \right|$$

$$b_{n-3} = \frac{-1}{a_{n-1}} \left| \begin{array}{cc} a_n & a_{n-4} \\ a_{n-1} & a_{n-5} \end{array} \right|$$

$$c_{n-1} = \frac{-1}{b_{n-1}} \left| \begin{array}{cc} a_{n-1} & a_{n-3} \\ b_{n-1} & b_{n-3} \end{array} \right|$$

The Routh-Hurwitz Stability Criterion

1. All coefficients of the characteristic polynomial must have the same sign and non-zero if all the roots are in the left-hand plane.
2. If there is no zero in first column of the Routh array.
 - System is stable if there is no sign change in the first column.
 - Number of sign changes in first column indicate number of poles in the RHS of s-plane. System is unstable.
2. If there is a zero only at first column of a row of the Routh array.
 - Replace zero with ϵ , then compute Routh array. Then find all elements in first column by taking limit value $\epsilon \rightarrow 0$.
 - Then if sign change in the first column system is unstable.
3. If all elements of a row is zero, then at least two poles are on imaginary axis. Poles those are on imaginary axis will be found from Auxiliary polynomials.

The Routh-Hurwitz Stability Criterion

Case One: No element in the first column is zero.

Example 6.1 Second-order system

The Characteristic polynomial of a second-order system is:

$$q(s) = a_2 \cdot s^2 + a_1 \cdot s + a_0$$

The Routh array is written as:

$$\begin{array}{c|cc} s^2 & a_2 & a_0 \\ s^1 & a_1 & 0 \\ s^0 & b_1 & 0 \end{array}$$

where:

$$b_1 = \frac{a_1 \cdot a_0 - (0) \cdot a_2}{a_1} = a_0$$

Therefore the requirement for a stable second-order system is simply that all coefficients be positive or all the coefficients be negative.

The Routh-Hurwitz Stability Criterion

Case Two: Zeros in the first column while some elements of the row containing a zero in the first column are nonzero.

If only one element in the array is zero, it may be replaced with a small positive number ε that is allowed to approach zero after completing the array.

$$q(s) = s^5 + 2s^4 + 2s^3 + 4s^2 + 11s + 10$$

The Routh array is then:

$$\begin{array}{c|ccc} s^5 & 1 & 2 & 11 \\ s^4 & 2 & 4 & 10 \\ s^3 & b_1 & 6 & 0 \\ s^2 & c_1 & 10 & 0 \\ s^1 & d_1 & 0 & 0 \\ s^0 & 10 & 0 & 0 \end{array}$$

where:

$$b_1 = \frac{2 \cdot 2 - 1 \cdot 4}{2} = 0 = \varepsilon \quad c_1 = \frac{4\varepsilon - 2 \cdot 6}{\varepsilon} = \frac{-12}{\varepsilon} \quad d_1 = \frac{6 \cdot c_1 - 10 \cdot 0}{c_1} = 6$$

There are two sign changes in the first column due to the large negative number calculated for c_1 . Thus, the system is unstable because two roots lie in the right half of the plane.

The Routh-Hurwitz Stability Criterion

Case Three: Zeros in the first column, and the other elements of the row containing the zero are also zero.

This case occurs when the polynomial $q(s)$ has zeros located symmetrically about the origin of the s -plane, such as $(s+\sigma)(s-\sigma)$ or $(s+j\omega)(s-j\omega)$. This case is solved using the auxiliary polynomial, $U(s)$, which is located in the row above the row containing the zero entry in the Routh array.

$$q(s) = s^3 + 2s^2 + 4s + K$$

Routh array:

$$\begin{array}{c|cc} s^3 & 1 & 4 \\ s^2 & 2 & K \\ s^1 & \frac{8-K}{2} & 0 \\ s^0 & K & 0 \end{array}$$

For a stable system we require that $0 < K < 8$

For the marginally stable case, $K=8$, the s^1 row of the Routh array contains all zeros. The auxiliary polynomial comes from the s^2 row.

$$U(s) = 2s^2 + Ks^0 = 2s^2 + 8 = 2(s^2 + 4) = 2(s + j2)(s - j2)$$

It can be proven that $U(s)$ is a factor of the characteristic polynomial:

$$\frac{q(s)}{U(s)} = \frac{s+2}{2}$$

Thus, when $K=8$, the factors of the characteristic polynomial are:

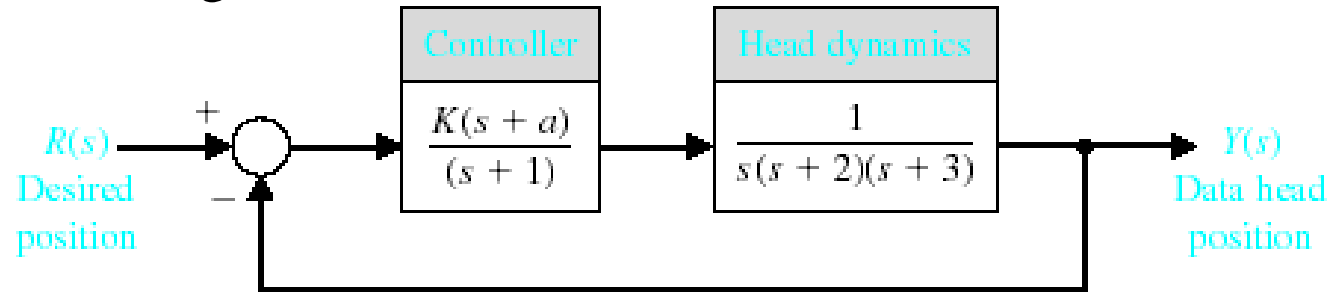

$$q(s) = (s+2)(s+j2)(s-j2)$$

The Routh-Hurwitz Stability Criterion

Case Four: Repeated roots of the characteristic equation on the $j\omega$ -axis.

With simple roots on the $j\omega$ -axis, the system will have a marginally stable behavior. This is not the case if the roots are repeated. Repeated roots on the $j\omega$ -axis will cause the system to be unstable. Unfortunately, the routh-array will fail to reveal this instability.

Example 6.5 Welding control

Welding head position control.

Using block diagram reduction we find that: $q(s) = s^4 + 6s^3 + 11s^2 + (K + 6)s + Ka$

The Routh array is then:

s^4	1	11	Ka
s^3	6	$(K + 6)$	
s^2	b_3	Ka	
s^1	c_3		
s^0	Ka		

$$\text{where: } b_3 = \frac{60 - K}{6} \quad \text{and} \quad c_3 = \frac{b_3(K + 6) - 6 \cdot Ka}{b_3}$$

For the system to be stable both b_3 and c_3 must be positive.

Using these equations a relationship can be determined for K and a .

The Relative Stability of Feedback Control Systems

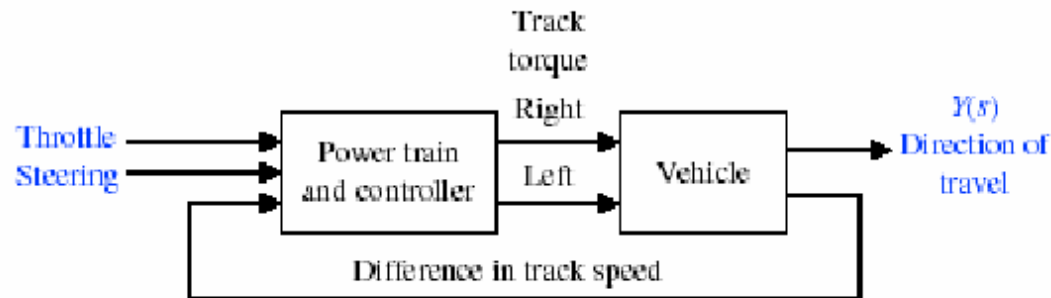

It is often necessary to know the relative damping of each root to the characteristic equation. Relative system stability can be measured by observing the relative real part of each root. In this diagram r_2 is relatively more stable than the pair of roots labeled r_1 .

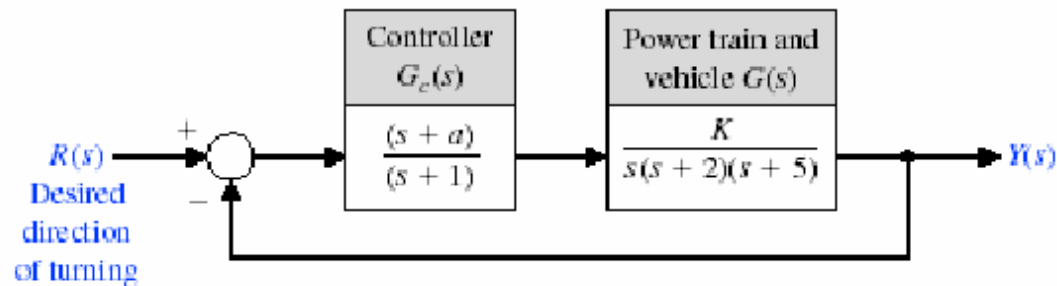

One method of determining the relative stability of each root is to use an axis shift in the s-domain and then use the Routh array as shown in Example 6.6 of the text.

Design Example: Tracked Vehicle Turning Control

Problem statement: Design the turning control for a tracked vehicle. Select K and a so that the system is stable. The system is modeled below.

(a)

(b)

Design Example: Tracked Vehicle Turning Control

The characteristic equation of this system is:

$$1 + G_c \cdot G(s) = 0$$

or

$$1 + \frac{K(s + a)}{s(s + 1)(s + 2)(s + 5)} = 0$$

Thus,

$$s(s + 1)(s + 2)(s + 5) + K(s + a) = 0$$

or

$$s^4 + 8s^3 + 17s^2 + (K + 10)s + Ka = 0$$

To determine a stable region for the system, we establish the Routh array as:

s^4	1	17	Ka
s^3	8	$(K + 10)$	0
s^2	b_3	Ka	
s^1	c_3		
s^0	Ka		

where

$$b_3 = \frac{126 - K}{8} \quad \text{and} \quad c_3 = \frac{b_3(K + 10) - 8Ka}{b_3}$$

Design Example: Tracked Vehicle Turning Control

s^4	1	17	Ka
s^3	8	$(K+10)$	0
s^2	b_3	Ka	
s^1	c_3		
s^0	Ka		

where

$$b_3 = \frac{126 - K}{8} \quad \text{and} \quad c_3 = \frac{b_3(K + 10) - 8Ka}{b_3}$$

Therefore,

$$K < 126$$

$$K \cdot a > 0$$

$$(K + 10)(126 - K) - 64Ka > 0$$

System Stability Using MATLAB

Closed-loop control system with $T(s) = Y(s)/R(s) = 1/(s^3 + s^2 + 2s + 23)$

```
>>numg=[1]; deng=[1 1 2 23]; sysg=tf(numg,deng);  
>>sys=feedback(sysg,[1]);  
>>pole(sys)
```

ans =

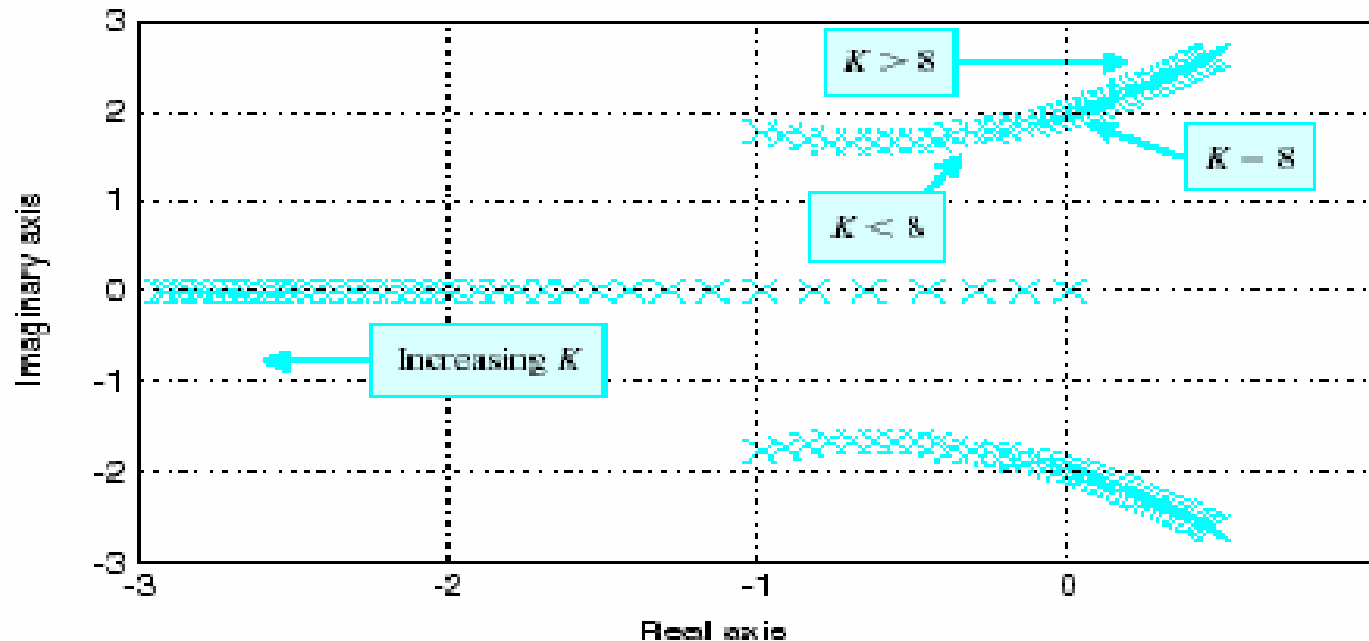

-3.0000

1.0000 + 2.6458i

1.0000 - 2.6458i

Unstable poles

System Stability Using MATLAB

(a)

```

% This script computes the roots of the characteristic
% equation q(s) = s^3 + 2 s^2 + 4 s + K for 0<K<20
%
K=[0:0.5:20];
for i=1:length(K)
    q=[1 2 4 K(i)];
    p(:,i)=roots(q);
end
plot(real(p),imag(p),'x'), grid
xlabel('Real axis'), ylabel('Imaginary axis')
    
```

← Loop for roots as a function of K

(b)

System Stability Using MATLAB

The for function and an illustrative example.

System Stability Using MATLAB

(a)

twotrackstable.m

```
% The a-K stability region for the two track vehicle
% control problem
%
a=[0.1:0.01:3.0]; K=[20:1:120];
x=zeros(1,length(K)); y=zeros(1,length(a));
n=length(K); m=length(a);
for i=1:n
    for j=1:m
        q=[1, 8, 17, K(i)+10, K(i)*a(j)];
        p=roots(q);
        if max(real(p)) > 0, x(i)=K(i); y(i)=a(j-1); break; end
    end
end
plot(x,y), grid, xlabel('K'), ylabel('a')
```

Annotations for the MATLAB script:

- Range of a and K : points to the initialization of a and K vectors.
- Initialize plot vectors as zero vectors of appropriate lengths.: points to the initialization of x and y vectors.
- Characteristic polynomial: points to the calculation of q .
- For a given value of K : determine first value of a for instability.: points to the inner loop where a is varied for a fixed K .

(b)

(a) Stability region for a and K for two-track vehicle turning control.

(b) MATLAB script.
